Unit 2 : Session 3 : SLO 2 | Introduction to Linked Lists

■ I. Fill in the Blanks

1. sequence (chain/collection) is a linked list is a sequence of data elements.
2. nodes are the data elements of a linked list.
3. foundation (base/building block) are linked lists underlie stacks, queues and their variants.
4. chain (sequence) of nodes is each node holds data field(s) and a pointer to the next node.
5. self-referential structure is a node points to another node of the same type.
6. address of the first node is START stores the first node's address.
7. START is traversal begins from START, following next pointers.
8. list is empty is START = NULL means the linked list is empty.
9. data (records/elements) is efficient storage with insertion, deletion and updation at the cost of extra pointer space.
10. C implementation: `struct node { int data; struct node *next; };`
